

# Chapter 7

10/20/20

# Dataset Types: Tables

# Design choices for arranging tables

## Arrange Tables

### ⊕ Express Values

### ⊕ Separate, Order, Align Regions

#### → Separate

#### → Order

#### → Align

#### → 1 Key *List*

#### → 2 Keys *Matrix*

#### → 3 Keys *Volume*

#### → Many Keys *Recursive Subdivision*

### ⊕ Axis Orientation

#### → Rectilinear

#### → Parallel

#### → Radial

### ⊕ Layout Density

#### → Dense

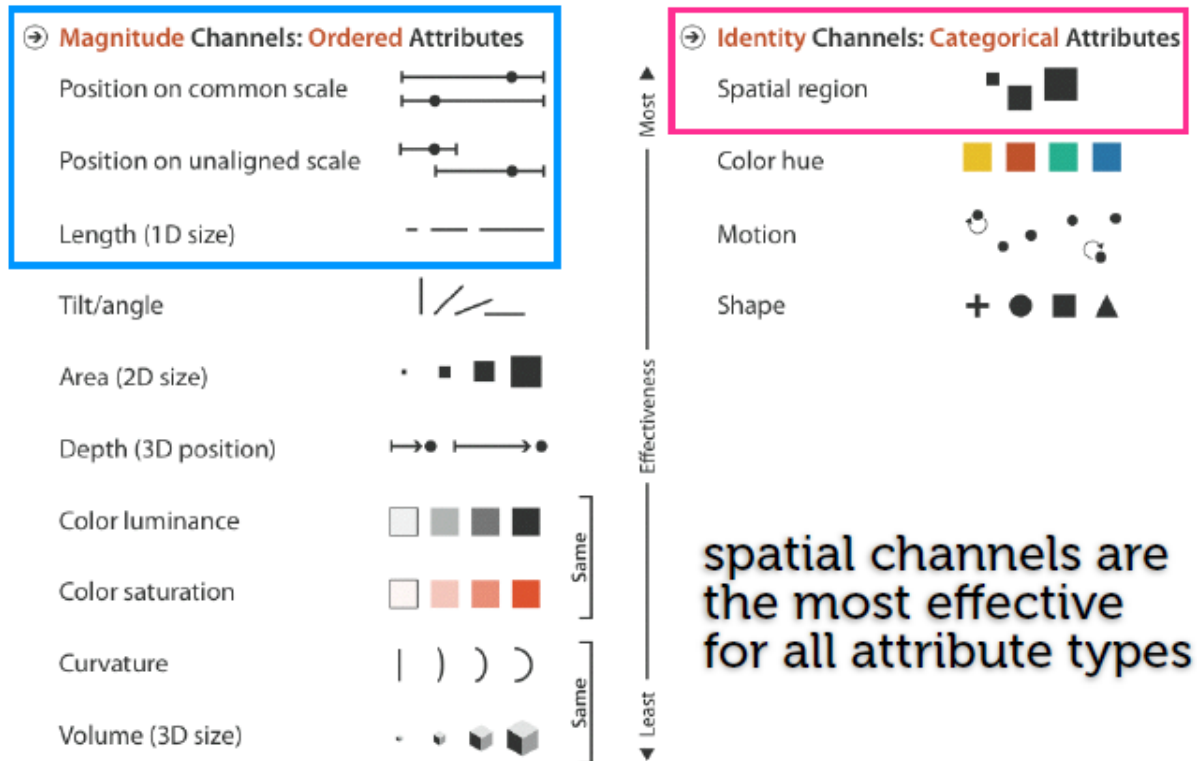

#### → Space-Filling

# Arrange

- Focus of all four design choices for tabular data

# Arrange by Keys and Values

- ▶ Key
  - ▶ Independent attribute that can be used as a unique index to look up items in a table
  - ▶ Categorical or ordinal
- ▶ Value
  - ▶ Dependent attribute; the value of a cell in a table
  - ▶ Can be all three of the types: categorical, ordinal, quantitative
  - ▶ Levels - unique values for a categorical or ordered attribute
- ▶ Examples:
  - ▶ Scatterplot - two value attributes
  - ▶ Bar charts - one key and one value attribute
  - ▶ Heatmap - two keys and one value attribute

# Express: Quantitative Values

- ▶ Plot example: Scatterplots
- ▶ Data: two quantitative values
- ▶ Task: find trends, clusters, outliers
- ▶ How: express values as point marks with horizontal and vertical spatial positioning
- ▶ Scalability: hundreds of points (items)
- ▶ Correlation: dependence between two attributes
  - ▶ Positive and negative correlation; indicated by lines
- ▶ Coordinate system (axes) and labels are important

# Separate, Order, and Align: Categorical Regions

- ▶ Spatial position - ordered magnitude visual channel
- ▶ Categorical attributes - unordered identity semantics
- ▶ Use spatial region, distinct contiguous bounded areas, to encode categorical attributes
- ▶ Break down the distribution of regions into three operations:
  - ▶ Separate (required) - done according to a categorical attribute
  - ▶ Align (optional) - done by some other attribute that is ordered
  - ▶ Order (required) - done by some other attribute that is ordered

## Arrange Tables

### ⊕ Express Values

### ⊕ Separate, Order, Align Regions

#### → Separate

#### → Order

#### → Align

### ⊕ Axis Orientation

#### → Rectilinear

#### → Parallel

#### → Radial

### ⊕ Layout Density

#### → Dense

#### → Space-Filling

# List Alignment: One Key Attribute

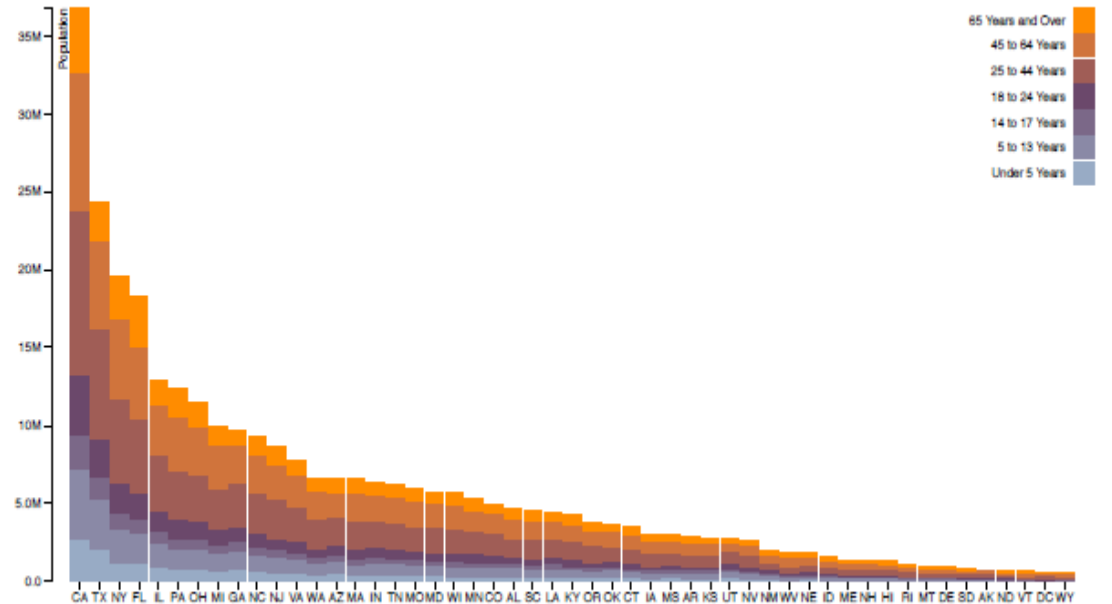

- ▶ Example: Bar Chart
- ▶ Data: one quantitative attribute, one categorical attribute
- ▶ Task: lookup and compare values
- ▶ How: line marks, horizontal position (categorical), vertical position (quantitative)
- ▶ Ordering criteria: alphabetical OR using quantitative attribute
- ▶ Scalability: distinguishability; hundreds

# List Alignment: One Key Attribute

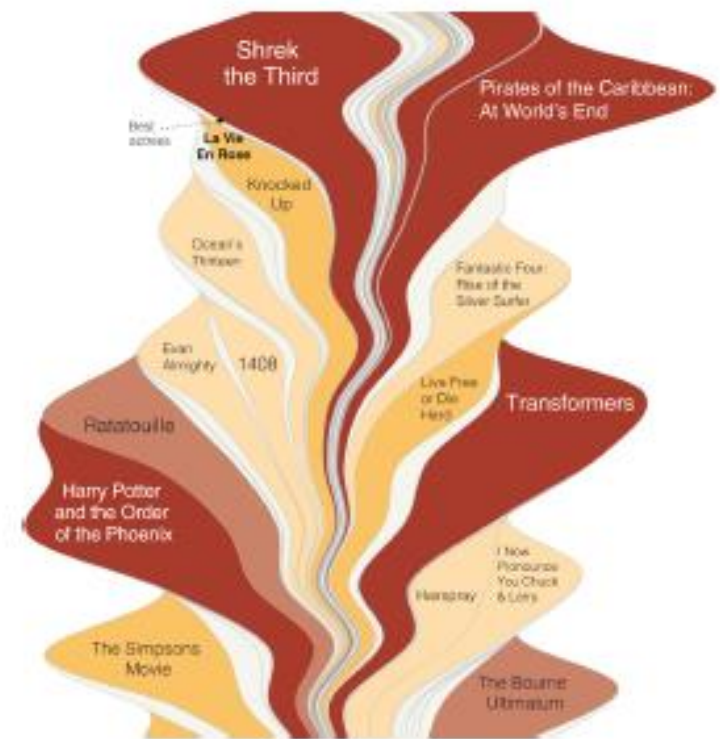

- ▶ Example: Stacked Bar Charts
- ▶ Data: multidimensional table: one quantitative attribute, two categorical attributes
- ▶ Task: lookup values, part-to-whole relationship, trends
- ▶ How:
  - ▶ line marks: position (both horizontal based on categorical and vertical (based on quantitative))
  - ▶ subcomponent line marks: length, color based on value attribute for each category of secondary key attribute
- ▶ Scalability: main axis (dozen to hundreds of levels), bar classes (stacked) (<12)

[Bostock, 2012]

# List Alignment: One Key Attribute

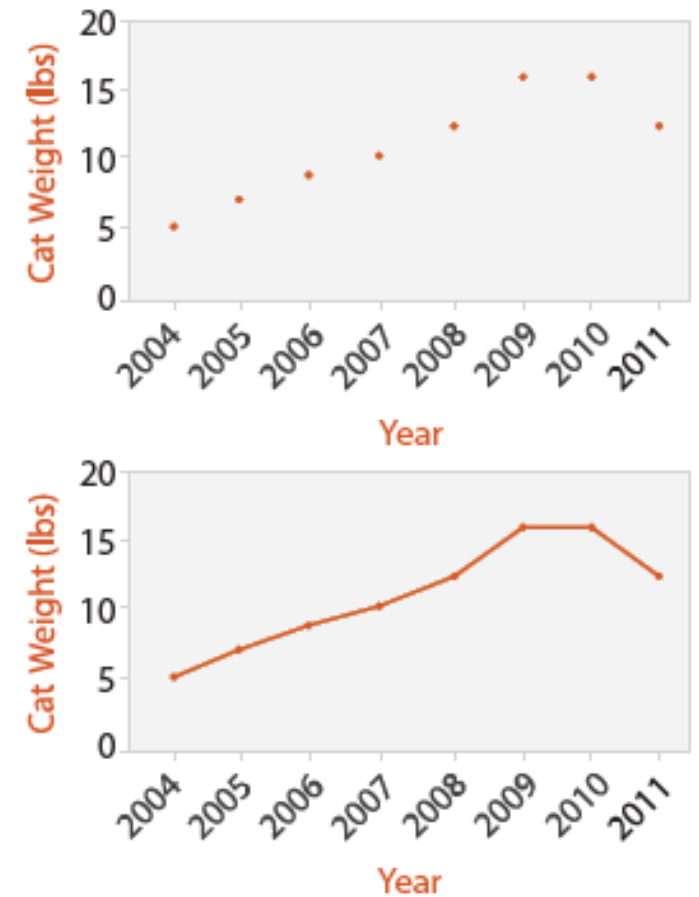

- ▶ Example: Steamgraphs
- ▶ Data: multidimensional table: one quantitative attribute (counts), one ordered key attribute (time), one categorical key attribute
- ▶ Task: analyze trends in time, find outliers
- ▶ How: derived position (height layer encodes counts) and geometry (categorical attribute across time)
- ▶ Scalability: more categories than stacked bar charts

[Byron and Wattenberg, 2012]

# List Alignment: One Key Attribute

- ▶ Example: Dot and Line Charts
- ▶ Data: one quantitative attribute, one ordered attribute
  - ▶ similar to scatterplots, but allows ordered attribute
- ▶ Task: lookup values, find outliers and trends
- ▶ How:
  - ▶ Dot charts: point mark and positions
  - ▶ Line charts: add connection mark (line)
- ▶ Scalability: key attribute can have hundreds of levels

# Proper Use of Line and Bar Charts

ok: "Men are taller than women  
(on average)"

bad: "The more male a person  
is, the taller he/she is"

Don't use line  
charts for  
categorical  
attributes!

ok: "Twelve year olds are taller  
than ten year olds"

ok: "Height increases with age"

# Matrix Alignment: Two Keys

- ▶ Example: Heatmaps
- ▶ Data: two categorical key attributes, one quantitative value attribute
- ▶ Task: find clusters, outliers, summarize
- ▶ How: area marks in grid, color encoding of quantitative attribute
- ▶ Scalability:
  - ▶ Items - one million
  - ▶ Categorical attribute levels - hundreds
  - ▶ Quantitative attribute levels - less than a dozen (colors)
- ▶ Note: be aware of colorblindness!

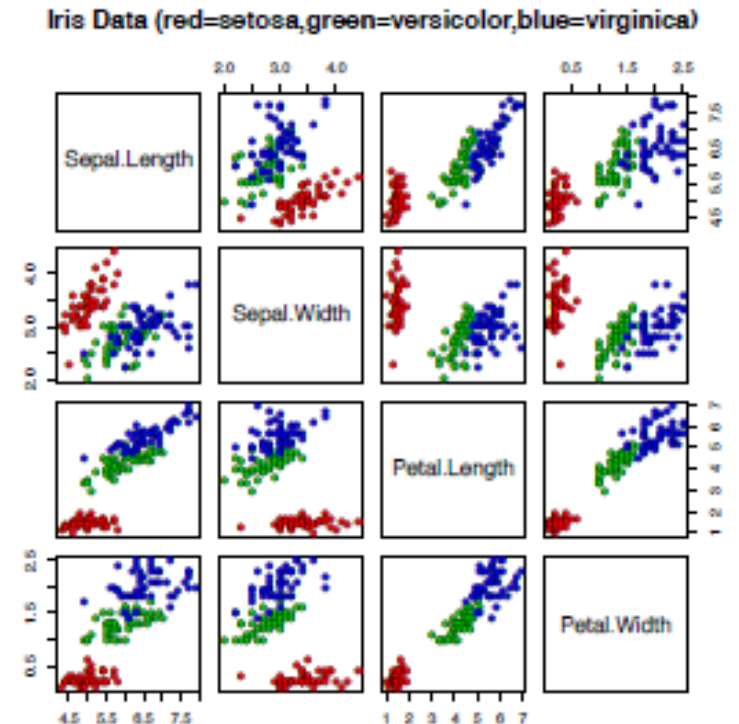

# Matrix Alignment: Two Keys

- ▶ Example: Cluster Heatmap
- ▶ Data: same as heatmap
- ▶ How: Area marks but matrix is ordered by two cluster hierarchies for table rows and columns
- ▶ Scalability: limited by the cluster dendrogram
- ▶ Dendrogram: a visual encoding of tree data with leaves aligned

# Matrix Alignment: Small-Multiple Views

- ▶ Example: scatterplot matrix (SPLOM)
- ▶ Data: many quantitative attributes (table)
- ▶ Task: find correlations, trends, outliers
- ▶ How: scatterplot in 2D matrix alignment
- ▶ Scale:
  - ▶ Attributes: about one dozen
  - ▶ Items: dozens to hundreds
- ▶ Visualizations in a visualization: at a higher level, marks are themselves visualizations

# Spatial Axis Orientation

- ▶ Rectilinear layouts (horizontal and vertical axes) have been used so far to encode almost everything!
- ▶ Are there other possibilities?

# Spatial Axis Orientation

- ▶ Rectilinear layouts (horizontal and vertical axes) have been used so far to encode almost everything!
- ▶ Are there other possibilities?
  - ▶ Parallel axes
  - ▶ Radial axes

# Parallel Coordinates

- Data: many quantitative attributes at once (using spatial position)
- Task: find trends, extremes, correlation
- How: vertical spatial position for each attribute, axis horizontally spaced (ordering horizontal axis is important), connection marks for identity (help visualize trends between particular values)
- Scalability: less than 40 attributes, hundreds of values
- Motivation: used for abstract task of checking for correlation between attributes

# Example

	V1	V2	V3	V4	V5
D1	7	3	4	8	1
D2	2	7	6	3	4
D3	9	8	1	4	2

# Comparing SPLOMs and Parallel Coordinates

Scatterplot Matrix

Parallel Coordinates

# Correlation in Parallel Coordinates

# Overdraw in Parallel Coordinates

# Radial Layouts

- ▶ Use Polar Coordinates
  - ▶ Angle and Length
  - ▶ Rectilinear and polar layouts same (mathematically)
  - ▶ Different, perceptually
  - ▶ What are the channel differences??

# Radial Layouts

- ▶ Angle channel is less accurately perceived
- ▶ Angle channel is inherently cyclic
- ▶ More effective in visualizing periodicity of patterns!
- ▶ Misleading to encode non-periodic data with radial layouts!
- ▶ Misleading if two attributes have equal importance b/c radial layouts imply an asymmetry of importance between two attributes

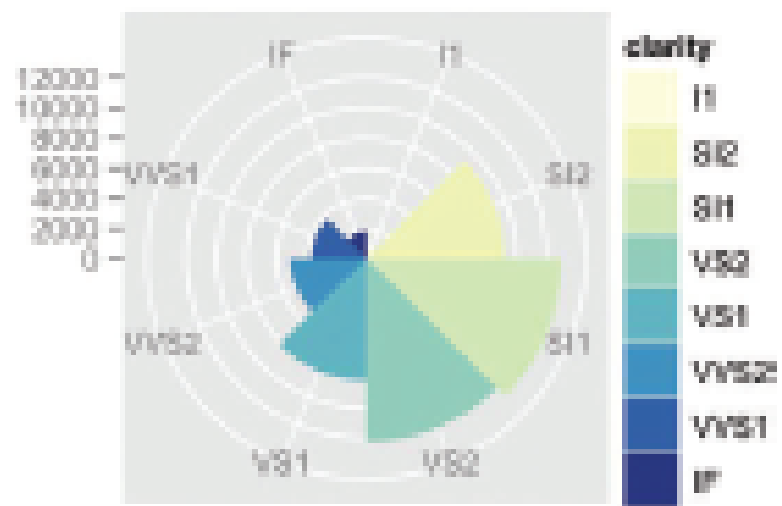

# Pie Chart

- ▶ Data: one quantitative, one categorical
- ▶ Task: part-whole relationship
- ▶ How: area marks using angle channels, radial layout
- ▶ Scalability: dozens of categories
- ▶ Color channel?
